Possible Billing Codes

The purpose of this document is to provide clinics and agencies with a list of prevention codes that the ROSES team feels meets the needs of providing a preventative education class such as ROSE. We encourage clinics/agencies to discuss the codes provided with their billing departments to determine if their ROSE facilitators/providers may seek reimbursement. While ROSE has been cited by the United States Preventative Task force as a prevention for perinatal depression, there is no standard method of billing ROSE across the country.

Questions to check for your plans:
1. What kind of providers can bill for these codes?
2. How often/how many times do most plans cover this code for a single person?
3. Are there restrictions to reimbursement for the listed codes for federally qualified health centers?

Under Education and Training for Patient Self-Management
Education and training for patient self-management by a qualified, non-physician health care professional using a standardized curriculum, face-to-face with the patient (could include caregiver/family)
- 98960- each 30 minutes; individual patient
  - ROSE can be delivered in a group setting or individually. This code would also be preferred for intervention visit 5
- 98961- each 30 minutes; 2-4 patients
- 98962- each 30 minutes; 5-8 patients

Counseling and/or Risk Factor Reduction Intervention
These codes are used to report services provided to individuals/groups at a separate encounter for the purpose of promoting health and preventing illness or injury. They are appropriate for initial or follow-up (new or established patient). For the specific preventive medicine counseling codes, the number of minutes counseled determines the level of billing.

Preventive Medicine, Individual Counseling
- 99401 Approximately 15 minutes.
- 99402 Approximately 30 minutes.
- 99403 Approximately 45 minutes.
- 99404 Approximately 60 minutes.

Preventive Medicine, Group Counseling
- 99411 Approximately 30 minutes.
- 99412 Approximately 60 minutes

Behavior Change Interventions, Individual Services
(provider example: medical doctor, nurse practitioner, physician assistant, clinical nurse practitioner)
These codes are for face-to-face counseling by a physician or other qualified health care professional, using “standardized, evidence-based screening instruments and tools with reliable documentation and appropriate sensitivity.”
- 99406 For intermediate visit of between 3 and 10 minutes.
- 99407 For an intensive visit lasting longer than 30 minutes.
The Affordable Care Act and Coverage of Preventative Services

Under the Affordable Care Act (ACA) there is now a national requirement that private health insurance plans and Medicaid expansion plans cover a basic set of preventive services without patient cost-sharing. These services include those recommended with an A or B grade by the U.S. Preventive Services Task Force (USPSTF). **ROSE (Reach Out Stay Strong Essentials) for pregnant and new moms received the USPSTF recommendation as a prevention for perinatal depression in February of 2019 with a B grade.**

Recognizing the critical importance of preventive services and care, ACA incorporated USPSTF recommendations into requirements for private and public health insurance coverage:

- **Private Plans.** All “new” (non-grandfathered) group and individual plans, both inside and outside of state Exchanges, must cover, without cost-sharing, all A and B recommended services.

- **Medicaid Expansion.** In states that are expanding Medicaid, the Medicaid expansion plans must cover all A and B recommended services without cost-sharing.

- **Traditional Medicaid.** While preventive services are still an optional benefit under traditional (non-expansion) Medicaid, ACA gives state Medicaid programs a financial incentive to cover preventive services. ACA offers states a 1% increase in FMAP if the state Medicaid program covers all A or B recommended services without cost-sharing; to qualify, the state must make these services available for both fee-for-service and managed care enrollees.

**Please note:** These services are free only when delivered by a doctor or other provider in a plan’s network.
Interventions to Prevent Perinatal Depression
US Preventive Services Task Force
Recommendation Statement

US Preventive Services Task Force

**IMPORTANCE** Perinatal depression, which is the occurrence of a depressive disorder during pregnancy or following childbirth, affects as many as 1 in 7 women and is one of the most common complications of pregnancy and the postpartum period. It is well established that perinatal depression can result in adverse short- and long-term effects on both the woman and child.

**OBJECTIVE** To issue a new US Preventive Services Task Force (USPSTF) recommendation on interventions to prevent perinatal depression.

**EVIDENCE REVIEW** The USPSTF reviewed the evidence on the benefits and harms of preventive interventions for perinatal depression in pregnant or postpartum women or their children. The USPSTF reviewed contextual information on the accuracy of tools used to identify women at increased risk of perinatal depression and the most effective timing for preventive interventions. Interventions reviewed included counseling, health system interventions, physical activity, education, supportive interventions, and other behavioral interventions, such as infant sleep training and expressive writing. Pharmacological approaches included the use of nortriptyline, sertraline, and omega-3 fatty acids.

**FINDINGS** The USPSTF found convincing evidence that counseling interventions, such as cognitive behavioral therapy and **interpersonal therapy**, are effective in preventing perinatal depression. Women with a history of depression, current depressive symptoms, or certain socioeconomic risk factors (eg, low income or young or single parenthood) would benefit from counseling interventions and could be considered at increased risk. The USPSTF found adequate evidence to bound the potential harms of counseling interventions as no greater than small, based on the nature of the intervention and the low likelihood of serious harms. The USPSTF found inadequate evidence to assess the benefits and harms of other noncounseling interventions. The USPSTF concludes with moderate certainty that providing or referring pregnant or postpartum women at increased risk to counseling interventions has a moderate net benefit in preventing perinatal depression.

**CONCLUSIONS AND RECOMMENDATION** The USPSTF recommends that clinicians provide or refer pregnant and postpartum persons who are at increased risk of perinatal depression to counseling interventions. (B recommendation)
The US Preventive Services Task Force (USPSTF) makes recommendations about the effectiveness of specific preventive care services for patients without obvious related signs or symptoms. It bases its recommendations on the evidence of both the benefits and harms of the service and an assessment of the balance. The USPSTF does not consider the costs of providing a service in this assessment.

The USPSTF recognizes that clinical decisions involve more considerations than evidence alone. Clinicians should understand the evidence but individualize decision making to the specific patient or situation. Similarly, the USPSTF notes that policy and coverage decisions involve considerations in addition to the evidence of clinical benefits and harms.

Summary of Recommendation and Evidence

The USPSTF recommends that clinicians provide or refer pregnant and postpartum persons who are at increased risk of perinatal depression to counseling interventions (B recommendation) (Figure 1). See the Clinical Considerations section for information on risk assessment.

USPSTF Levels of Certainty Regarding Net Benefit

<table>
<thead>
<tr>
<th>Level of Certainty</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>High</td>
<td>The available evidence usually includes consistent results from well-designed, well-conducted studies in representative primary care populations. These studies assess the effects of the preventive service on health outcomes. This conclusion is therefore unlikely to be strongly affected by the results of future studies.</td>
</tr>
<tr>
<td>Moderate</td>
<td>The available evidence is sufficient to determine the effects of the preventive service on health outcomes, but confidence in the estimate is constrained by such factors as the number, size, or quality of individual studies. Inconsistency of findings across individual studies. Limited generalizability of findings to routine primary care practice. Lack of coherence in the chain of evidence. As more information becomes available, the magnitude or direction of the observed effect could change, and this change may be large enough to alter the conclusion.</td>
</tr>
<tr>
<td>Low</td>
<td>The available evidence is insufficient to assess effects on health outcomes. Evidence is insufficient because of the limited number or size of studies. Important flaws in study design or methods. Inconsistency of findings across individual studies. Gaps in the chain of evidence. Findings not generalizable to routine primary care practice. Lack of information on important health outcomes. More information may allow estimation of effects on health outcomes. The USPSTF defines certainty as “likelihood that the USPSTF assessment of the net benefit of a preventive service is correct.” The net benefit is defined as benefit minus harm of the preventive service as implemented in a general, primary care population. The USPSTF assigns a certainty level based on the nature of the overall evidence available to assess the net benefit of a preventive service.</td>
</tr>
</tbody>
</table>

USPSTF indicates US Preventive Services Task Force.
Perinatal depression, which is the occurrence of a depressive disorder during pregnancy or following childbirth, affects as many as 1 in 7 women and is one of the most common complications of pregnancy and the postpartum period. It is well established that perinatal depression can result in negative short- and long-term effects on both the woman and child.

Benefits of Counseling Interventions
The USPSTF found convincing evidence that counseling interventions, such as cognitive behavioral therapy and interpersonal therapy, are effective in preventing perinatal depression in those at increased risk.

Harms of Counseling Interventions
The USPSTF found adequate evidence to bound the potential harms of counseling interventions as no greater than small, based on the nature of the interventions and the low likelihood of serious harms.

USPSTF Assessment
The USPSTF concludes with moderate certainty that counseling interventions to prevent perinatal depression have a moderate net benefit for persons at increased risk.

Patient Population Under Consideration
This recommendation applies to pregnant persons and persons who are less than 1 year postpartum who do not have a current diagnosis of depression but are at increased risk of developing depression (Figure 2).

Assessment of Risk
Clinical risk factors that may be associated with the development of perinatal depression include a personal or family history of depression, history of physical or sexual abuse, having an unplanned or unwanted pregnancy, current stressful life events, pregestational or gestational diabetes, and complications during pregnancy (eg, preterm delivery or pregnancy loss). In addition, social factors such as low socioeconomic status, lack of social or financial support, and adolescent parenthood have also been shown to increase the risk of developing perinatal depression. However, there is no accurate screening tool for identifying women at risk of perinatal depression and who might benefit from preventive interventions.

A pragmatic approach, based on the populations included in the systematic evidence review, would be to provide counseling interventions to women with 1 or more of the following risk factors: a history of depression, current depressive symptoms (that do not reach a diagnostic threshold), certain socioeconomic risk factors such as low income or adolescent or single parenthood, recent intimate partner violence, or mental health-related factors such as elevated anxiety symptoms or a history of significant negative life events.

For a summary of the evidence systematically reviewed in making this recommendation, the full recommendation statement, and supporting documents, please go to https://www.uspreventiveservicestaskforce.org.

USPSTF indicates US Preventive Services Task Force.

The USPSTF recommends screening for depression in adults, including pregnant and postpartum women. The USPSTF also recommends screening for depression in adolescents aged 12 to 18 years and found insufficient evidence to recommend for or against screening in children 11 years or younger.
Counseling Interventions
Studies on counseling interventions to prevent perinatal depression mainly included cognitive behavioral therapy and interpersonal therapy.

Cognitive behavioral therapy focuses on the concept that positive changes in mood and behavior can be achieved by addressing and managing negative thoughts, beliefs, and attitudes and by increasing positive events and activities. Common therapeutic techniques include patient education, goal-setting, interventions to identify and modify maladaptive thought patterns, and behavioral activation. Interpersonal therapy focuses on treating interpersonal issues thought to contribute to the development or maintenance of psychological disorders. Common therapeutic techniques include the use of exploratory questions (ie, open-ended and clarifying questions), role-playing, decision analysis, and communication analysis. The interventions reviewed by the USPSTF varied in setting, intensity, format, and intervention staff. Counseling intervention trials included a mixture of populations at increased risk of perinatal depression and not at increased risk.

The USPSTF found limited or mixed evidence that other studied interventions such as physical activity, education, pharmacotherapy, dietary supplements, and health system interventions were effective in preventing perinatal depression.

Implementation
There are no data on the ideal timing for offering or referral to counseling interventions; however, most were initiated during the second trimester of pregnancy. Ongoing assessment of risks that develop in pregnancy and the immediate postpartum period would be reasonable, and referral could occur at any time.

Counseling sessions reviewed for this recommendation ranged from 4 to 20 meetings (median, 8 meetings) lasting for 4 to 70 weeks. The format of counseling consisted mainly of group and individual sessions, with the majority involving in-person visits. Intervention staff included psychologists, midwives, nurses, and other mental health professionals.

One example of a cognitive behavioral approach was the "Mothers and Babies" program. It involved 6 to 12 weekly 1- to 2-hour group sessions during pregnancy and 2 to 5 postpartum booster sessions. The program included modules on the cognitive behavioral theory of mood and health; physiological effects of stress; the importance of pleasant and rewarding activities; how to reduce cognitive distortions and automatic thoughts; and the importance of social networks, positive mother-child attachment, and parenting strategies to promote child development and secure attachment in infants.

The Reach Out, Stand Strong, Essentials for New Mothers (ROSE) program is an example of an interpersonal therapy approach reviewed by the USPSTF. It involved 4 or 5 prenatal group sessions lasting 60 to 90 minutes and 1 individual 50-minute postpartum session. Course content included psychoeducation on the "baby blues" and postpartum depression, stress management, development of a social support system, identification of role transitions, discussion of types of interpersonal conflicts common around childbirth and techniques for resolving them, and role-playing exercises with feedback from other group members.

Additional Approaches to Prevention of Depression
The Substance Abuse and Mental Health Administration—Health Resources and Services Administration Center for Integrated Health Solutions promotes the development of, and provides resources for, integrating primary and behavioral health services. The Substance Abuse and Mental Health Administration provides resources for locating mental health services.

The Mothers and Babies program, which is based on cognitive behavioral therapy, also provides web-based resources for families and clinicians.

The USPSTF has a related recommendation on screening for depression in adults, including pregnant and postpartum women (B recommendation). The USPSTF also recommends screening for depression in adolescents aged 12 to 18 years (B recommendation) and found insufficient evidence to recommend for or against screening in children 11 years or younger (I statement).

Other Considerations
Research Gaps and Needs
Further research could address important gaps in several areas. Good-quality evidence is lacking on the best way to identify women at increased risk of perinatal depression who would most benefit from preventive interventions. Measures of depression symptoms are useful in predicting future perinatal depression, although more data are needed on how to incorporate other perinatal risk factors into these depression screening tools.

A small number of trials examined several potentially valuable depression prevention interventions, such as physical activity, infant sleep education, in-hospital perinatal education, and peer counseling. More and larger-scale trials of these types of interventions are needed to expand the evidence base. Similarly, large-scale trials of cognitive behavioral therapy and interpersonal therapy interventions are needed to demonstrate whether these strategies are scalable and applicable to persons at lower risk.

Several interventions related to improved health systems, such as developing clinical pathways, training health care practitioners, and facilitating access to embedded behavioral health specialists, show promise and have been implemented on a limited basis in US-based primary care settings. Further research is needed to evaluate the potential benefits and harms of these types of interventions.

Data are lacking on the benefits and harms of antidepressant medications for the prevention of perinatal depression. Likewise, dietary supplements, such as selenium and vitamin D, have shown promise, but more research is needed to explore these interventions.

Discussion
Burden of Disease
Perinatal depression is the occurrence of a depressive disorder during pregnancy or following childbirth. Symptoms include loss of interest and energy, depressed mood, fluctuations in sleep or eating patterns, reduced ability to think or concentrate, feelings of worthlessness, and recurrent suicidal ideation. Symptoms of depressed mood or loss of interest are required and must be present for a minimum of 2 weeks. The diagnosis should not be confused with the less severe...
postpartum “baby blues,” which is a commonly experienced transient mood disturbance consisting of crying, irritability, fatigue, and anxiety that usually resolves within 10 days of delivery.21

In the United States, the estimated prevalence of major depressive disorder in the postpartum period ranges from 8.9% among pregnant women to 37% at any point in the first year postpartum.22 Rates vary by age, race/ethnicity, and other sociodemographic characteristics. For example, women 19 years or younger, American Indian/Alaska Native women, women with less than 12 years of education, unmarried women, or women with 6 or more stressful life events in the previous 12 months have higher reported rates of perinatal depression.23

It is well established that depression during the postpartum period can lead to adverse effects on the mother and infant. Although acts of harming oneself or the fetus or newborn are rare, perinatal depression increases the risk of suicide and suicidal ideation, and mothers with depression report more thoughts of harming their infants than mothers without depression.24 Women with perinatal depression exhibit significantly higher levels of negative maternal behaviors (ie, hostile or coercive behaviors or both) and disengagement from their infants than women without perinatal depression.25 Women with perinatal depression are also more likely to exhibit significantly lower levels of positive maternal behaviors, such as praising and playing with their child.26 Perinatal depression is linked to an increased risk of preterm birth, small for gestational age newborn, and low birth weight.26 Infants whose mothers have perinatal depression are at increased risk of early cessation of breastfeeding27 and have been shown to receive fewer preventive health services (ie, vaccinations) compared with infants whose mothers are without depressive symptoms.28 Perinatal depression can also affect a child’s cognition and emotional development. Children of mothers who had perinatal depression demonstrate more behavior problems, lower cognitive functioning, and increased risk of developing psychiatric disorders.29,30

Risk Factors
A number of risk factors are thought to be associated with the development of perinatal depression. These include a past history of depression,31 current depressive symptoms (that do not reach a diagnostic threshold),32 history of physical or sexual abuse,33,34 unplanned or unwanted pregnancy,35 stressful life events,23,31 lack of social and financial support,31,33 intimate partner violence,33,34 pregestational or gestational diabetes,36 and complications during pregnancy. Additional risk factors include adolescent parenthood, low socioeconomic status, and lack of social support.37 Genetic factors are also suspected to contribute to women’s risk of developing perinatal depression.38

Scope of Review
The USPSTF commissioned a systematic evidence review2,6 to evaluate the evidence on the potential benefits and harms of preventive interventions for perinatal depression in pregnant or postpartum women or their children. The review focused on studies of interventions involving pregnant women and new mothers of any age who were both selected and unselected based on known risk factors. The review included studies of women with mental health symptoms or disorders, although studies targeting women with a depression diagnosis, women with high levels of depressive symptoms, or women currently being treated for a depressive disorder were excluded, as were studies of women with psychotic or developmental disorders. The USPSTF reviewed contextual information on the accuracy of tools used to identify women at increased risk of perinatal depression and the most effective timing for preventive interventions. Interventions reviewed included counseling, health system interventions, physical activity, education, supportive interventions, and other behavioral interventions, such as infant sleep training and expressive writing. Pharmacological approaches included the use of nortriptyline, sertraline, and omega-3 fatty acids.

Effectiveness of Preventive Interventions
The USPSTF reviewed studies of pregnant and postpartum women who received interventions to prevent perinatal depression delivered in or referred from primary care. The main reported outcomes were depression status (measured as cumulative incidence, point prevalence, or scoring above a cutoff on a symptom severity scale) and continuous depression symptom scale scores. Other health outcomes such as quality of life, infant or child outcomes, and functioning were also reported by trials and considered by the USPSTF. The USPSTF reviewed a total of 50 good- or fair-quality studies (49 randomized clinical trials, 1 nonrandomized controlled intervention study). The studies were divided between those that targeted pregnant (26/50 [52%]) or postpartum (22/50 [44%]) women. Two trials recruited pregnant women as well as women up to 26 weeks postpartum. Most studies (42/50 [84%]) were limited to women 18 years or older, and the mean age across studies was 28.6 years. Twenty-six of the studies (52%) selected women with risk factors for perinatal depression. These included a personal or family history of depression (or perinatal depression), elevated depressive symptoms, socioeconomic factors (eg, low income, single or without partner, young age, or recent intimate partner violence), and other mental health factors (elevated anxiety symptoms or history of significant negative life events). The majority of participants in the included studies were non-Hispanic white women, although 2 studies were limited to Latina women and 8 had a majority black and Latina population. Nearly one-fourth of the included studies (13/50 [26%]) were primarily or entirely composed of economically disadvantaged women.2

Twenty trials (n = 4107) reported on counseling interventions. More than half were conducted in the United States (12/20 [60%]), most were limited to adults (older than 18 years) (17/20 [85%]), and most initiated interventions during pregnancy (17/20 [85%]). Three-quarters of the trials were limited to women known to be at increased risk of perinatal depression because of depression history or symptoms (6/20 [30%]); non–depression-related risk factors such as low socioeconomic status, recent intimate partner violence, or young age (3/20 [15%]); or depression-related or other risk factors (6/20 [30%]). Almost two-thirds (13/20 [65%]) of the trials excluded women who met diagnostic criteria for current major depression or scored above the cutoff on a symptom severity scale. Most of the interventions (13/20 [65%]) used cognitive behavioral therapy or interpersonal therapy approaches. Counseling interventions lasted a median of 8 weeks and had a median of 12 hours of total contact time. The interventions consisted of both group (15/20 [75%]) and individual (11/20 [55%]) sessions, with some involving both types. Settings included in-person (19/20) or telephone-based meetings (2/20), and 4 trials included home visits. Across all
counseling interventions, half to three-quarters of sessions were attended by participants.  

When the outcomes of incidence, prevalence, and scoring above the cutoff on a symptom severity scale were combined, counseling interventions were associated with a 39% reduction in the likelihood of perinatal depression (pooled relative risk [RR], 0.61 [95% CI, 0.47 to 0.78]). Assuming a 19% baseline risk of perinatal depression (ie, the median percentage of women with depression in control groups at 3 to 6 months postpartum across all included studies), this corresponds to a number needed to treat of 13.5 women (95% CI, 9.9 to 23.9). Compared with the overall effect of counseling interventions, studies reporting the use of cognitive behavioral therapy or interpersonal therapy approaches showed similar effects.  

Subgroup analysis of trials using the "Mothers and Babies" and ROSE programs showed pooled RR reductions of 53% and 50%, respectively. When analyzing the effect of counseling interventions by study population, trials that selected women at increased risk of perinatal depression (based on symptoms, history of depression, or social or socioeconomic risk factors) demonstrated a larger positive effect compared with trials enrolling lower-risk, unselected populations (45% vs 21% risk reduction, respectively), although this difference was not statistically significant.  

Thirteen trials reported continuous symptom score measures, with 5 trials demonstrating statistically significant group differences. Counseling interventions were associated with a small beneficial effect in symptom scores, resulting in a pooled standardized effect size of 0.2, or an average 1.5-point greater reduction in depression symptom severity compared with control groups. Trials reported other maternal or child outcomes; however, outcome measures varied widely and there was little consistency across studies. Stress (4 trials) and anxiety (4 trials) were the most common other reported outcomes, although most trials did not demonstrate statistically significant findings.  

Three studies (n = 5321) examined health system–level interventions consisting of screening, counseling, and patient navigation services conducted by midwives and nurses. In all 3 studies, usual care included home visitation.  

Individually, each study showed a statistically significant risk reduction in the likelihood of scoring above the cutoff on the Edinburgh Postnatal Depression Scale (EPDS) (RR range, 0.33 to 0.71). However, pooled analysis did not demonstrate statistical significance (RR, 0.58 [95% CI, 0.22 to 1.53]). Three trials (n = 1200) examined physical activity programs consisting of group or individual exercise sessions (with or without dietary advice or educational sessions). Two trials found statistically significant reductions in depression symptoms (weighted mean difference, −3.45 [95% CI, −4.99 to −1.91]), although pooled analysis failed to demonstrate statistically significant reductions in depression diagnosis (RR, 0.54 [95% CI, 0.18 to 1.57]).  

Three trials (n = 980) focusing on improving infant sleep demonstrated mixed results. One trial found a 39% reduction in the likelihood of scoring 10 or higher on the EPDS at 6-month follow-up (adjusted odds ratio, 0.57 [95% CI, 0.34 to 0.94]). Two other trials reported statistically significant or near-significant reductions in symptom severity scores at 1 (but not all) of several time points on at least 1 depression screening instrument (but not all). Educational interventions and other supportive interventions, such as telephone-based peer support and nondirective group sessions, demonstrated inconsistent findings, with 1 of 6 and 3 of 7 trials, respectively, reporting statistically significant reductions in depression status or depression symptom scores. Yoga classes, debriefing exercises, and expressive writing failed to demonstrate statistically significant reductions in depression symptoms or status.  

Four trials of chemoprevention of perinatal depression assessed the effects of sertraline (n = 22), nortriptyline (n = 58), and omega-3 fatty acids (n = 219). The sertraline trial found that at 20 weeks postpartum, women taking sertraline had decreased depression recurrence compared with those taking placebo (7% vs 50%, respectively; P = .04). In addition, the time to depression recurrence was faster in participants receiving placebo (P = .02). Neither nortriptyline nor omega-3 fatty acids showed preventive benefits for perinatal depression compared with placebo, although omega-3 fatty acids demonstrated small statistically significant improvements in gestational length, mean birth weight, and 5-minute Apgar score.  

Potential Harms of Preventive Interventions  

The nortriptyline trial reported only the number of events for 1 of 11 adverse effects, with 78% of women taking nortriptyline reporting constipation (vs 22% of women taking placebo). Participants taking sertraline were more likely than those taking placebo to report dizziness (57% vs 13%, respectively; P = .05) and drowsiness (100% vs 50%, respectively; P = .02). One woman taking nortriptyline and 1 woman taking sertraline developed mania or hypomania, but there were no cases among women taking placebo. No harms were associated with omega-3 fatty acids. None of the other included intervention trials reported harms outcomes.  

Estimate of Magnitude of Net Benefit  

The USPSTF found convincing evidence that counseling interventions, such as cognitive behavioral therapy and interpersonal therapy, are effective in preventing perinatal depression. Based on the population of women included in the studies, those with a history of depression, current depressive symptoms, or certain socioeconomic risk factors (eg, low income or young or single parenthood) would benefit from counseling interventions and could be considered at increased risk. The USPSTF found adequate evidence to bound the potential harms of counseling interventions as no greater than small, based on the nature of the intervention and the low likelihood of serious harms. The USPSTF found inadequate evidence to assess the benefits and harms of other noncounseling interventions. The USPSTF concludes with moderate certainty that providing or referring pregnant or postpartum women at increased risk to counseling interventions has a moderate net benefit in preventing perinatal depression.  

Response to Public Comment  

A draft version of this recommendation statement was posted for public comment on the USPSTF website from August 28 to September 24, 2018. Several comments requested that the recommendation be expanded to include associated mood disorders (such as anxiety disorder). The primary focus of the USPSTF recommendation and evidence review was depression. Several additional outcomes (including anxiety) were included in the scope of the evidence review; however, reporting on incidence or symptoms of anxiety was limited and inconsistent. Several comments questioned why perinatal...
depression screening tools such as the EPDS were not recommended as risk-assessment tools. Additionally, comments requested that the USPSTF clarify the population at risk that would benefit from counseling interventions. The focus of this recommendation is the prevention of depression; the USPSTF has a separate recommendation on screening for depression in all adults, including pregnant women. The Research Gaps and Needs section calls for more studies on the use of tools for risk assessment, including established screening tools. For this recommendation, the USPSTF defined increased risk based on the study population; the USPSTF made revisions to further identify who would be considered at increased risk of depression. Several comments raised concerns about the ability of clinicians to implement the recommendation because of barriers to accessing mental health services. The USPSTF recognizes these barriers and provided some additional information about mental health resources and systems to connect patients to appropriate care in the Implementation section and Additional Approaches to Prevention of Depression section.

Recommendations of Others

The USPSTF found no other guidelines on the prevention of perinatal depression. The American College of Obstetricians and Gynecologists recommends early postpartum follow-up care, including screening for depression and anxiety, for all postpartum women.19,59

All members of the USPSTF receive travel reimbursement and an honorarium for participating in USPSTF meetings.

Funding/Support: The USPSTF is an independent, voluntary body. The US Congress mandates that the Agency for Healthcare Research and Quality (AHRQ) support the operations of the USPSTF.

Role of the Funder/Sponsor: AHRQ staff assisted in the following: development and review of the research plan, commission of the systematic evidence review from an Evidence-based Practice Center, coordination of expert review and public comment of the draft evidence report and draft recommendation statement, and the writing and preparation of the final recommendation statement and its submission for publication. AHRQ staff had no role in the approval of the final recommendation statement or the decision to submit for publication.

Disclaimer: Recommendations made by the USPSTF are independent of the US government. They should not be construed as an official position of AHRQ or the US Department of Health and Human Services.

Additional Contributions: We thank Justin Mills, MD, MPH (AHRQ), who contributed to the writing of the manuscript, and Lisa Nicoletta, MA (AHRQ), who assisted with coordination and editing.
